ABOUT ME

Biomedical engineer with clinical experience supporting complex electrophysiology procedures and working directly with physicians to evaluate cardiac arrhythmias and catheter ablation therapies.

I currently work at Johnson & Johnson (Biosense Webster) supporting electrophysiology procedures using CARTO electroanatomical mapping technology to map cardiac arrhythmias and support ablation procedures. Through this work, I collaborate closely with physicians, troubleshoot advanced medical technologies in real-time, and observe procedural workflows to identify opportunities for device improvement and better patient outcomes. This experience has given me firsthand insight into how physicians interact with medical technologies and how device design influences procedural efficiency and patient outcomes.

My background combines engineering design, human anatomy, and clinical workflow knowledge. During graduate studies at the University at Buffalo, I conducted cadaver research evaluating tissue preservation methods for surgical training and medical device testing environments. I have also developed 3D-printed orthopedic and anatomical models used for surgical education and device prototyping.

I am particularly interested in roles where clinical insight informs product development, including positions in medical devices, surgical robotics, orthopedic technologies, and human performance or fitness wearables. My long-term goal is to help design technologies that improve patient care and enhance human performance.

I am especially interested in opportunities in the **Bay Area, San Diego, and Boston**, where medical device innovation and wearable technology development are rapidly advancing.
